

# **Shortest Path Trees and Reach in Road Networks**

Louis Abraham & Sayuli Drouard

# Our subject: shortest paths

- Given a starting point, where do  $t$  **hours** on a **shortest path** bring you ?
- What if your **destination** is at least  $t'$  **hours** away ?
- Study of the notion of **reach** (option B)

# Method for Part I

- Given a starting point, where do  $t$  **hours** on a **shortest path** bring you ?

} Dijkstra implemented with binary

- What if your **destination** is at least  $t'$  **hours** away ?

} Compute shortest paths using Dijkstra, then select vertices further away than  $t'$ , and backtrack to a  $t$  distance

# Optimization

- **Dijkstra stop**
- **Dijkstra memoization**
- **Distance sorting**
- **Online Dijkstra**

## Part II (Option B)

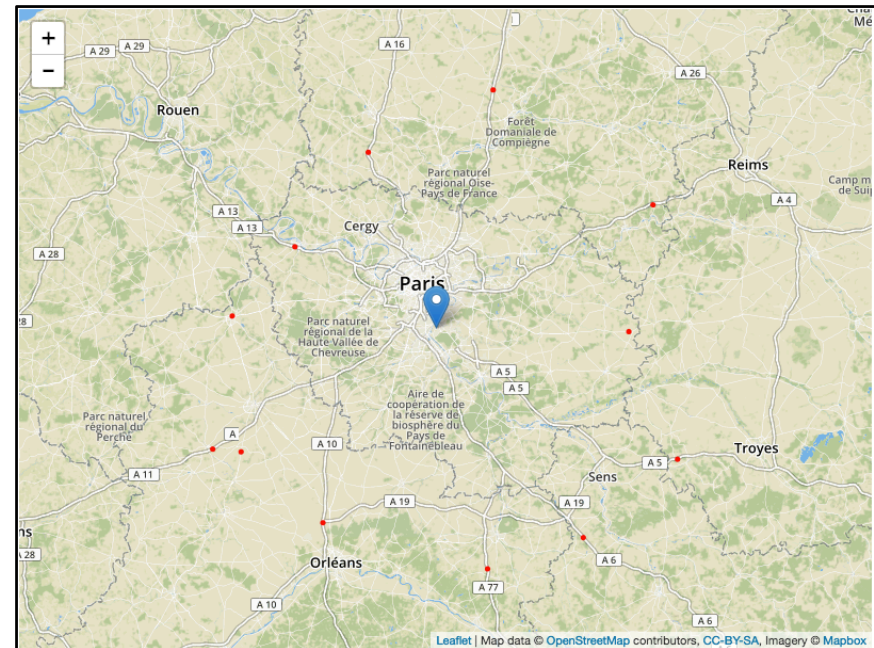

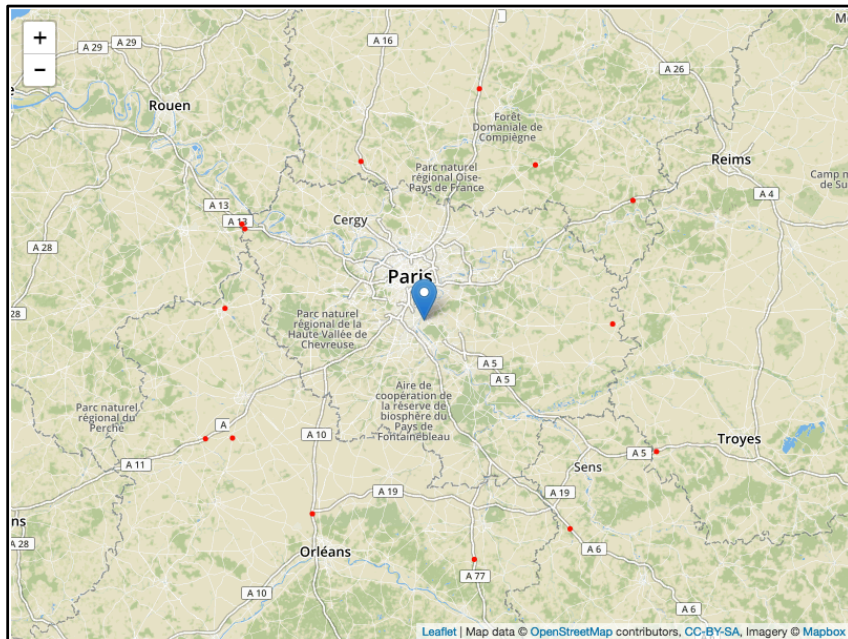

**The notion of reach**

# Part II (Option B)

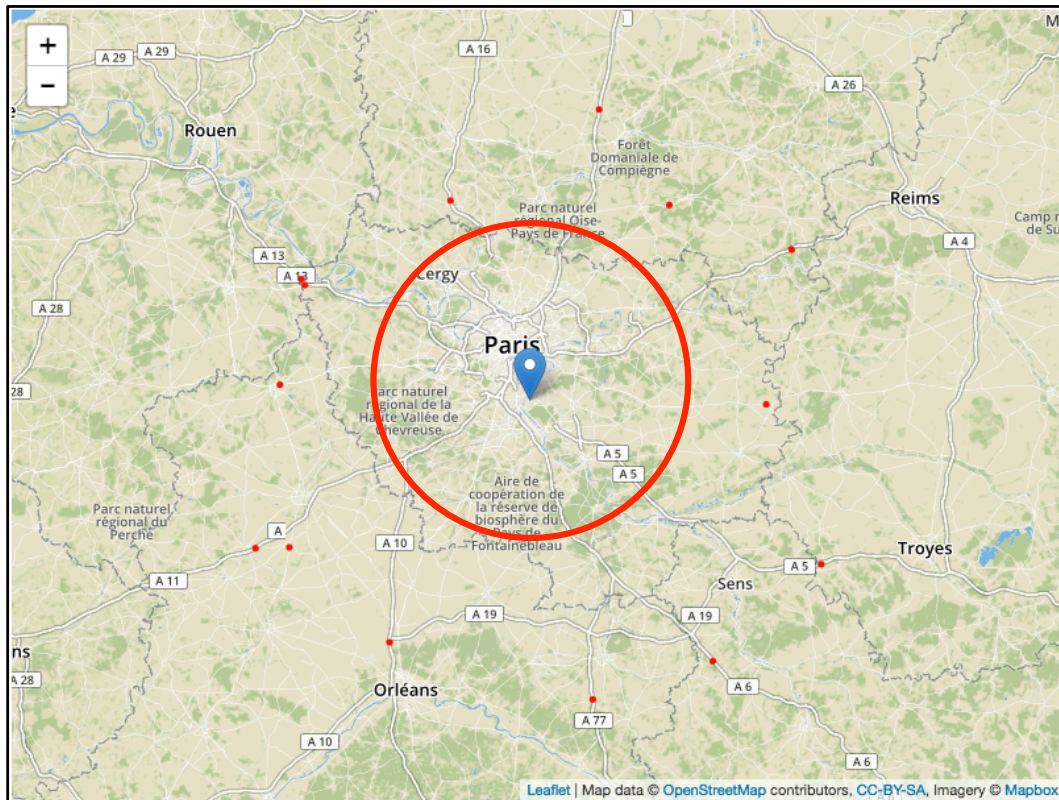

$T_{out}$  = set of points  
from problem (1.3)

$S_{in}$  : same definition as  
 $T_{out}$  with the converse  
graph

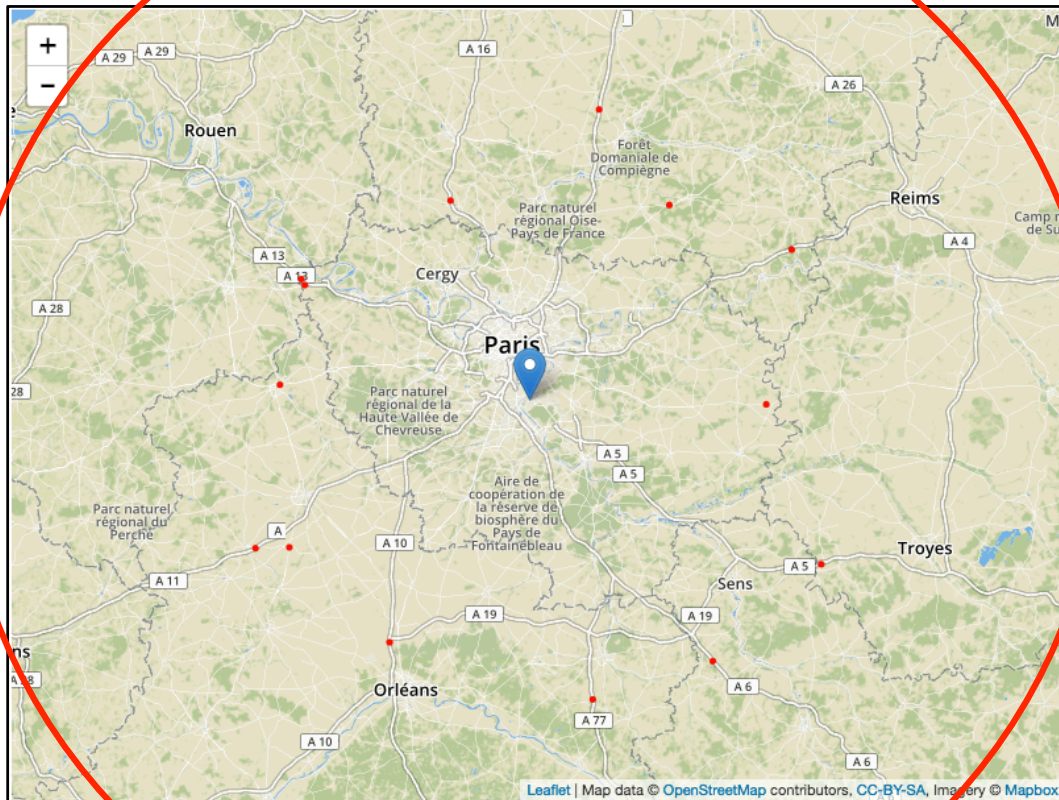

# Part II (Option B)

If  $\text{reach}(v) < 1$   
hour :

NO shortest path  
joins  $S_{in}$  and  $T_{out}$   
through  $v$

## Part II (Option B)

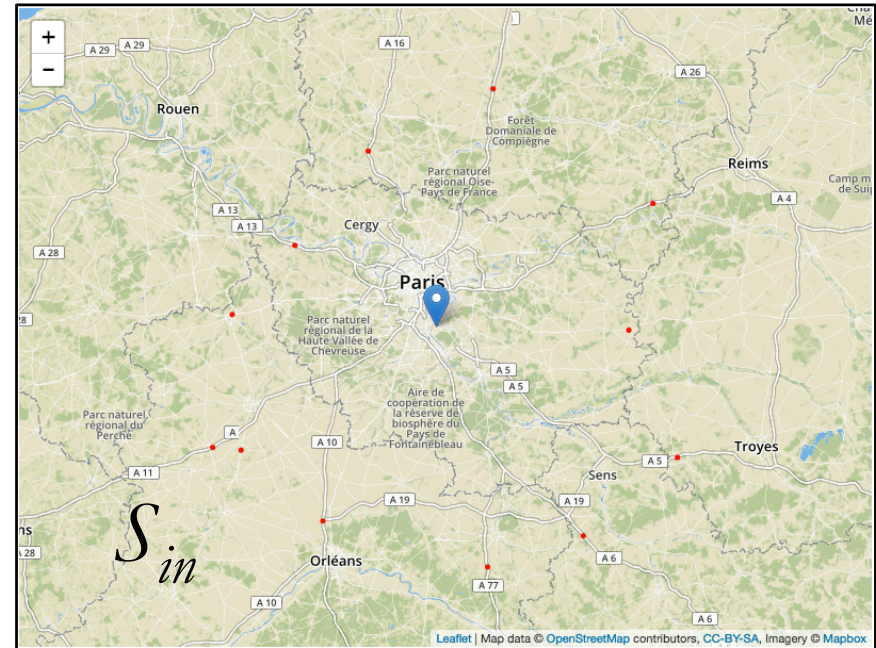

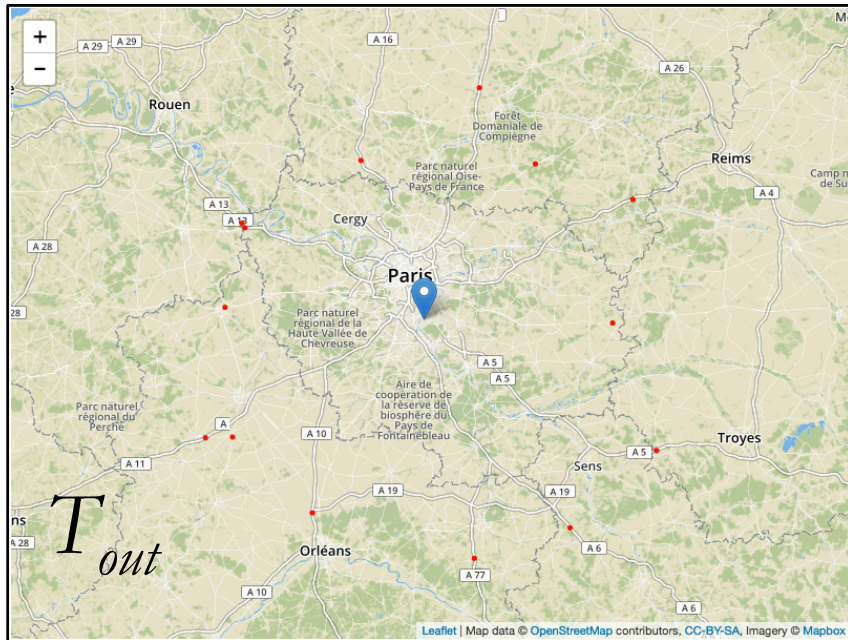

If  $\text{reach}(v) \geq 2$   
hours :

There MUST be a  
shortest path  
joining  $S_{in}$  and  
 $T_{out}$  through  $v$

# Part II (Option B)

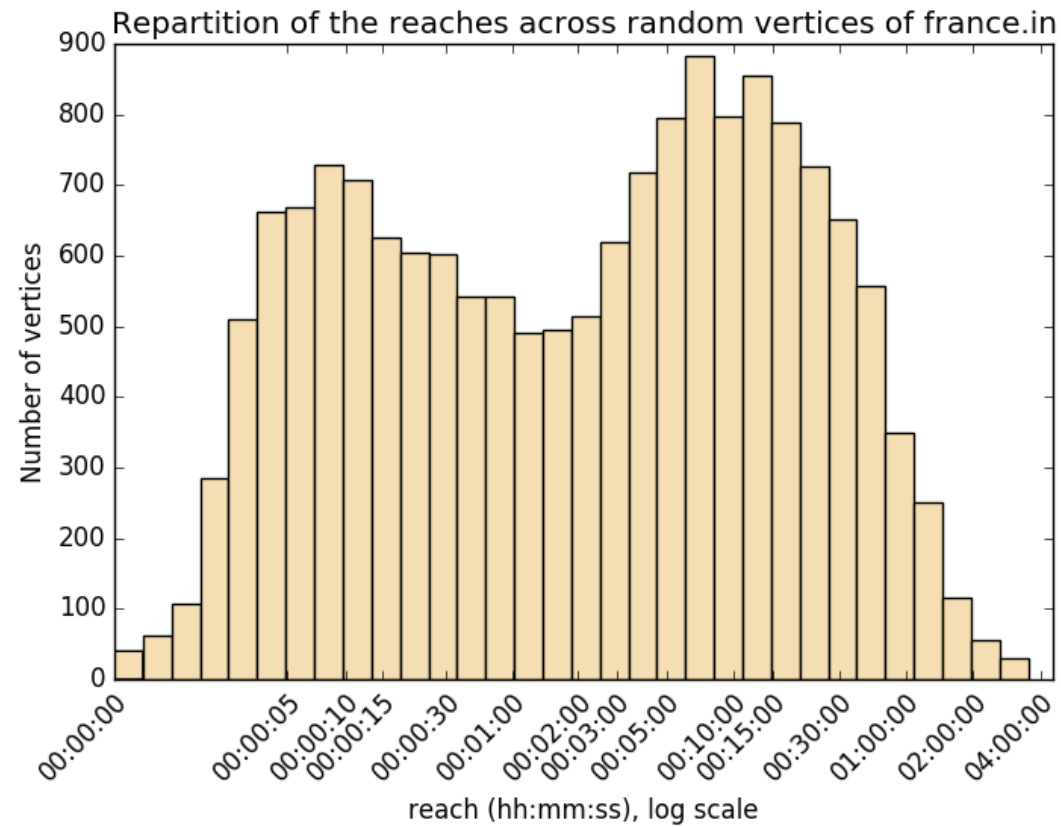

The algorithm: estimating **reach**( $v$ )

# Reach in France

# Reach in France

Thank you.
